

Graded context-loss ablation: neighbour information dominates, but collapse requires BOTH local and neighbour context to fail together (interaction effect)

*PRECIP mask fixed at MCAR-10 (416 identical masked positions in every panel); error bars = ± 1 SD over 3 context-mask seeds $\times$ 3 model seeds ($n=9$ /point).
Adjacency uses $k=2$ neighbours per station. Local-loss and neighbour-loss varied independently before joint-loss.*
